Appendix F	Cost-effectiveness analysis	242
Appendix	Recommendations for research	278

Appendix A

SCOPE

1 Guideline title

Glaucoma: diagnosis and management of chronic open angle glaucoma and ocular hypertension

1.1 Short title

Glaucoma

2 Background

a) The National Institute for Health and Clinical Excellence ('NICE' or 'the Institute') has commissioned the National Collaborating Centre for Acute Care to develop a clinical guideline on the diagnosis and management of chronic open angle glaucoma and ocular hypertension for use in the NHS in England and Wales. This follows referral of the topic by the Department of Health (see section 6). The guideline will provide recommendations for good practice that are based on the best available evidence of clinical and cost effectiveness.

b) The Institute's clinical guidelines will support the implementation of National Service Frameworks (NSFs) in those aspects of care where a Framework has been published. The statements in each NSF reflect the evidence that was used at the time the Framework was prepared. The clinical guidelines and technology appraisals published by the Institute after an NSF has been issued will have the effect of updating the Framework.

c) NICE clinical guidelines support the role of healthcare professionals in providing care in partnership with patients, taking account of their individual needs and preferences, and ensuring that patients (and their carers and families, where appropriate) can make informed decisions about their care and treatment.

3 Clinical need for the guideline

a) Approximately 10% of UK blindness registrations are ascribed to glaucoma. It is estimated that in the UK about 2% of people older than 40 have chronic open angle glaucoma, and this rises to almost 10% in people older than 75. With changes in population demographics the number of people affected by glaucoma is expected to rise.

b) Chronic open-angle glaucoma tends to be asymptomatic and therefore many people will not notice any symptoms until severe visual damage has occurred. Population-based screening programmes are being considered and the Department of Health's National Screening Committee is undertaking a review of screening programmes due to be published in 2007.

c) Recent national guidelines on glaucoma include 'Guidelines for the management of open angle glaucoma and ocular hypertension' (Royal College of Ophthalmologists, 2004). The Department of Health Do Once And Share project has also developed a glaucoma pathway and dataset (2006).

d) There is a clinical need for a guideline on diagnosis and management of chronic open angle glaucoma because this is a common and potentially blinding condition associated with uncertainty and variation in clinical practice in a number of areas. These include:

- an agreed case definition for ocular hypertension and chronic open angle glaucoma
- an agreed terminology incorporating the influence of raised intraocular pressure (that is, primary open angle glaucoma compared with normal tension glaucoma)
- agreement on when to treat chronic open angle glaucoma and how aggressively to do so
- agreement on whether to treat (simple) ocular hypertension
- which tests should be standard or optional for purposes of diagnosis and chronic disease monitoring
- how frequently patients should be followed up for chronic disease monitoring purposes and whether this interval should vary with perceived disease 'severity'
- who should monitor glaucoma, where this should be undertaken and whether different care providers should be used depending on perceived disease 'severity'

4 The guideline

a) The guideline development process is described in detail in two publications that are available from the NICE website (see 'Further information'). 'The guideline development process: an overview for stakeholders, the public and the NHS' describes how organisations can become involved in the development of a guideline. 'The guidelines manual' provides advice on the technical aspects of guideline development.

b) This document is the scope. It defines exactly what this guideline will (and will not) examine, and what the guideline developers will consider. The scope is based on the referral from the Department of Health (see appendix).

c) The areas that will be addressed by the guideline are described in the following sections.

4.1 Population

4.1.1 Groups that will be covered

a) Adults (18 and older) with a diagnosis of chronic open angle glaucoma or ocular hypertension. That is, individuals who, in the presence of open or narrow (but not occludable or closed) anterior chamber angles have one or more of the following features:

- glaucomatous visual field loss
- glaucomatous optic neuropathy
- raised intraocular pressure.

b) People with chronic open angle glaucoma or ocular hypertension associated with pseudoexfoliation or pigment dispersion.

c) People who have higher prevalence of glaucoma and may have worse clinical outcomes including:

- people with a family history of glaucoma,
- younger people (<50 years)
- people who are of black African or black Caribbean descent

4.1.2 Groups that will not be covered

a) People younger than 18 years.

b) People with secondary glaucoma (for example neovascular or uveitic) except for those described in 4.1.1 b.

c) People with, or at risk of, primary or secondary angle closure glaucoma.

d) Adults with primary congenital, infantile or childhood glaucoma.

4.2 Healthcare setting

a) Community, primary care, secondary care outpatient and day treatment services, and tertiary care specialist services

4.3 Clinical management

a) The diagnosis of chronic open angle glaucoma and ocular hypertension in patients presenting at community optometrists and those referred to hospital eye services using one or more of the tests below:

- measurement of intraocular pressure
- visual field test
- optic nerve head assessment
- anterior chamber angle assessment.

b) The appropriate use of pharmacological interventions, for example effectiveness, cost effectiveness, initiation and duration of treatment. Pharmacological treatments considered will include:

- eye drops
 - beta blockers
 - prostaglandin related drugs
 - sympathomimetics
 - carbonic anhydrase inhibitors
 - miotics
- systemic medications
 - carbonic anhydrase inhibitors

Note that guideline recommendations will normally fall within licensed indications; exceptionally, and only where clearly supported by evidence, use outside a licensed indication may be recommended. The guideline will assume that prescribers will use a drug's summary of product characteristics to inform their decisions for individual patients.

c) The effectiveness of penetrating and nonpenetrating surgical drainage procedures with and without pharmacological augmentation or drainage devices.

d) The effectiveness of postsurgical drain manipulation with and without the use of pharmacological augmentation.

e) The effectiveness of laser procedures to facilitate aqueous outflow or reduce aqueous production.

- f) The information, education and support needs of patients to achieve treatment concordance will be considered.
- g) The most appropriate service models, where evidence of clinical and cost effectiveness is available.
- h) The guideline development group will consider making recommendations on the principal complementary and alternative interventions or approaches to care relevant to the guideline topic.
- i) The guideline development group will take reasonable steps to identify ineffective interventions and approaches to care. If robust and credible recommendations for re-positioning the intervention for optimal use, or changing the approach to care to make more efficient use of resources can be made, they will be clearly stated. If the resources released are substantial, consideration will be given to listing such recommendations in the 'Key priorities for implementation' section of the guideline.
- j) Population based screening programmes for glaucoma are not within the remit of this guideline.

4.4 Status

4.4.1 Scope

This is the final scope.

4.4.2 Guideline

The development of the guideline recommendations will begin in June 2007.

Associated NICE Guidance Medicines Concordance (in development) for publication December 2008.

5 Further information

Information on the guideline development process is provided in:

- 'The guideline development process: an overview for stakeholders, the public and the NHS'
- 'The guidelines manual'.

These booklets are available as PDF files from the NICE website (www.nice.org.uk/guidelinesmanual). Information on the progress of the guideline will also be available from the website.

6 Referral from the Department of Health

The Department of Health asked the Institute:

'To prepare a clinical guideline on the diagnosis and management of chronic open angle glaucoma and ocular hypertension (raised intraocular pressure). The guideline should include recommendations on the most appropriate service models where evidence of effectiveness is available.'

Appendix B

1 Declarations of interests

1.1 Introduction

All members of the GDG and all members of the NCC-AC staff were required to make formal declarations of interest at the outset, and these were updated at every subsequent meeting throughout the development process. No interests were declared that required actions.

1.2 Declarations of interests of the GDG members

Ms Cecilia Fenerty.....	p. 9
Ms Wendy Franks.....	p. 10
Ms Mary Freeman.....	p. 11
Mr Dennis Keight.....	p. 12
Ms Susana Ramirez-Florez.....	p. 13
Ms Safina Rashid	p. 14
Mr John Sparrow (Chair)	p. 15
Mr Paul Spry.....	p. 16
Mr Chris Steele	p. 17
Ms Sheila Urquhart... ..	p. 18
Mr Richard Wormald	p. 19
Mr David Wright.....	p. 20

1.2.1 Ms Cecilia Fenerty

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	She declared a personal pecuniary interest: she is a glaucoma speciality ophthalmic consultant working for the NHS with a subspecialty interest in glaucoma. She declared two non-personal pecuniary interests: her place of work, Manchester Royal Eye Hospital, received an award from Allergan in 2006 for £2500. She also received a Pfizer grant for research into persistence with glaucoma therapy (this research was not product specific). She declared no personal family interests or personal non-pecuniary interests.
Second GDG Meeting (25th June 2007)	No change to declarations
Third GDG Meeting (26th July 2007)	No change to declarations
Fourth GDG Meeting (11th September 2007)	No change to declarations
Fifth GDG Meeting (24th October 2007)	No change to declarations
Sixth GDG Meeting (5th December 2007)	The declarations above plus: She declared a non-personal pecuniary interest: she received a donation of drop aids from Alcon for a study into compliance. This device is product specific as it can only be used with Travatan/Duotrav. The trial itself was not funded by Alcon.
Seventh GDG Meeting (29th January 2008)	No change to declarations
Eight GDG Meeting (13th March 2008)	No change to declarations
Ninth GDG Meeting (25th April 2008)	No change to declarations
Tenth GDG Meeting (19th May 2008)	No change to declarations
Eleventh GDG Meeting (3rd June 2008)	No change to declarations
Twelfth GDG Meeting (9th July 2008)	No change to declarations
Thirteenth GDG Meeting (31st July 2008)	No change to declarations

1.2.2 Ms Wendy Franks

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	She declared a personal pecuniary interest: she is a glaucoma specialist employed by Moorfields Eye Hospital NHS Trust and undertakes work in private practice. She declared a non-personal pecuniary interest: she received sponsorship for studies from Alcon, Allergan and Pfizer in her capacity as Director of Glaucoma contract research, a post she relinquished upon joining the GDG. She declared a personal non-pecuniary interest: she has published papers about her views of effectiveness of medical treatments. She declared no personal family interests.
Second GDG Meeting (25th June 2007)	She did not attend this meeting.
Third GDG Meeting (26th July 2007)	The declarations above plus: She declared a non-personal pecuniary interest: her department has received grants from the pharmaceutical industry.
Fourth GDG Meeting (11th September 2007)	She did not attend this meeting.
Fifth GDG Meeting (24th October 2007)	No change to declarations
Sixth GDG Meeting (5th December 2007)	She did not attend this meeting.
Seventh GDG Meeting (29th January 2008)	The declarations above plus: She declared a personal pecuniary interest: she received an honorarium of €2000 covering travel/subsistence expenses to speak at the Rotterdam Glaucoma Club in January 2008. The lectures were not related to any company products. The meeting had sponsorship from Alcon.
Eight GDG Meeting (13th March 2008)	No change to declarations
Ninth GDG Meeting (25th April 2008)	No change to declarations
Tenth GDG Meeting (19th May 2008)	No change to declarations
Eleventh GDG Meeting (3rd June 2008)	No change to declarations
Twelfth GDG Meeting (9th July 2008)	No change to declarations
Thirteenth GDG Meeting (31st July 2008)	No change to declarations

1.2.3 Ms Mary Freeman

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	She did not attend this meeting.
Second GDG Meeting (25th June 2007)	She declared a personal pecuniary interest: she received an honorarium from Novartis for speaking at an annual nurse symposium on age related macular degeneration in 2006 and 2007. Novartis also supported the attendance of an annual international conference in September '06 on "Advances in Wet AMD" by providing reasonable accommodation and travel expenses. Alcon supported the attendance of a meeting for specialist nurses on glaucoma by providing reasonable mileage cost and overnight accommodation in Hemel Hempstead. She sees NHS glaucoma patients. She declared no personal family interest, non-personal pecuniary interest, or personal non-pecuniary interest.
Third GDG Meeting (26th July 2007)	No change to declarations
Fourth GDG Meeting (11th September 2007)	No change to declarations
Fifth GDG Meeting (24th October 2007)	No change to declarations
Sixth GDG Meeting (5th December 2007)	No change to declarations
Seventh GDG Meeting (29th January 2008)	No change to declarations
Eight GDG Meeting (13th March 2008)	The declarations above plus: She declared a non-personal pecuniary interest: she is a study co-ordinator for a phase 3 trial using Macugen for diabetic maculopathy supported by Pfizer.
Ninth GDG Meeting (25th April 2008)	No change to declarations
Tenth GDG Meeting (19th May 2008)	No change to declarations
Eleventh GDG Meeting (3rd June 2008)	No change to declarations
Twelfth GDG Meeting (9th July 2008)	No change to declarations
Thirteenth GDG Meeting (31st July 2008)	The declarations above plus: She declared a personal pecuniary interest: She was invited to speak at the annual Nurse symposium 2008 sponsored by Novartis on AMD. She accepted reasonable hospitality (overnight accommodation and transport). She declined an honorarium which was instead made payable to a hospital charitable fund. Post meeting she declared a personal non-pecuniary interest: She has had an article accepted for publication in Eye News on the glaucoma referral scheme in Sheffield. Due for publication Oct/Nov 08. She declared two personal pecuniary interests: She has also been invited to chair and speak at an educational meeting on glaucoma for nurses in Doncaster in November 08 sponsored by Allergan. She declined an honorarium and her speaker fees will be paid to the Trust. She has also invited to speak at the Royal College of Nursing (RCN) conference on the glaucoma referral scheme in Sheffield in September 08 for which she accepted reasonable overnight accommodation and transport cost reimbursement.

1.2.4 Mr Dennis Keight

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	<p>He declared a personal pecuniary interest: he owns shares in Astrazeneca and his pension is paid by Astrazeneca. Astrazeneca do not manufacture any drugs within this guideline.</p> <p>He declared a personal family interest: his wife is employed by Western Cheshire PCT as an IT project manager. His wife also acts as a consultant for Informing Healthcare (Wales) as a Health Data Consultant.</p> <p>He declared a personal non-pecuniary interest: he is a member of the International Glaucoma Association.</p> <p>He declared no non-personal pecuniary interest.</p>
Second GDG Meeting (25th June 2007)	No change to declarations
Third GDG Meeting (26th July 2007)	No change to declarations
Fourth GDG Meeting (11th September 2007)	No change to declarations
Fifth GDG Meeting (24th October 2007)	He did not attend this meeting.
Sixth GDG Meeting (5th December 2007)	No change to declarations
Seventh GDG Meeting (29th January 2008)	No change to declarations
Eight GDG Meeting (13th March 2008)	He amended his personal family interest: His wife is no longer employed directly by Western Cheshire PCT but occasionally undertakes consultancy work for them.
Ninth GDG Meeting (25th April 2008)	No change to declarations
Tenth GDG Meeting (19th May 2008)	No change to declarations
Eleventh GDG Meeting (3rd June 2008)	No change to declarations
Twelfth GDG Meeting (9th July 2008)	No change to declarations
Thirteenth GDG Meeting (31st July 2008)	No change to declarations

1.2.5 Ms Susana Ramirez-Florez

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	She declared two non-personal pecuniary interests: She is an NHS Consultant Ophthalmologist and also undertakes work in private practice. Additionally the Department of Health, through the modernisation agency awarded Peterborough District Hospital, where she is employed, a grant of £422000 for the Glaucoma Community Optometrist Project. She declared no personal family interests or personal non-pecuniary interests.
Second GDG Meeting (25th June 2007)	No change to declarations
Third GDG Meeting (26th July 2007)	No change to declarations
Fourth GDG Meeting (11th September 2007)	The declarations above plus: She declared a non-personal pecuniary interest: she took part in a visual field workshop for ophthalmic doctors in Peterborough which were sponsored by Allergan.
Fifth GDG Meeting (24th October 2007)	No change to declarations
Sixth GDG Meeting (5th December 2007)	No change to declarations
Seventh GDG Meeting (29th January 2008)	No change to declarations
Eight GDG Meeting (13th March 2008)	The declarations above plus: She declared two non-personal pecuniary interests: Peterborough & Stamford NHS Foundation Trust, her employer, distributed 60 posters designed by the Glaucoma Alliance Group lead by the RNIB to GP practices which were printed by Allergan, Alcon and Pfizer. After prior approval from NICE she was nominated for an award from Allergan, and was given travel expenses and accommodation to the venue after the Annual Ophthalmological Congress in Liverpool.
Ninth GDG Meeting (25th April 2008)	The declarations above plus: She declared a non-personal pecuniary interest: Her place of work is a pilot site for the Sibling Awareness Project led by the RNIB.
Tenth GDG Meeting (19th May 2008)	No change to declarations
Eleventh GDG Meeting (3rd June 2008)	The declarations above plus: She declared a personal non-pecuniary interest: she was invited to a Merck Sharp and Dohme glaucoma meeting on 2 November 2008.
Twelfth GDG Meeting (9th July 2008)	The declarations above plus: She declared a non-personal pecuniary interest: Peterborough & Stamford NHS Foundation Trust was awarded 3rd place in the recent Allergan glaucoma awards and the prize of £3,000 will be spent on equipment for glaucoma care.
Thirteenth GDG Meeting (31st July 2008)	No change to declarations

1.2.6 Ms Safina Rashid

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	She did not attend this meeting.
Second GDG Meeting (25th June 2007)	She declared a personal pecuniary interest: she is an NHS employee. She declared no personal family interest, non-personal pecuniary interest, or personal non-pecuniary interest.
Third GDG Meeting (26th July 2007)	No change to declarations
Fourth GDG Meeting (11th September 2007)	She did not attend this meeting.
Fifth GDG Meeting (24th October 2007)	The declarations above plus: She declared a personal pecuniary interest: she is the NHS Chair for BIOS (British and Irish Orthoptic Society).
Sixth GDG Meeting (5th December 2007)	She did not attend this meeting.
Seventh GDG Meeting (29th January 2008)	No change to declarations
Eight GDG Meeting (13th March 2008)	No change to declarations
Ninth GDG Meeting (25th April 2008)	No change to declarations
Tenth GDG Meeting (19th May 2008)	The declarations above plus: She declared a non-personal pecuniary interest: she led a teaching programme for nurses and optometrists which was sponsored by Pfizer via a £400 donation to the departmental research fund.
Eleventh GDG Meeting (3rd June 2008)	She did not attend this meeting.
Twelfth GDG Meeting (9th July 2008)	She did not attend this meeting.
Thirteenth GDG Meeting (31st July 2008)	She did not attend this meeting

1.2.7 Mr John Sparrow

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	He declared a personal pecuniary interest: he is an NHS employee caring for glaucoma patients. He is a member of a limited liability partnership, the Consultant Eye Surgeons Partnership which delivers both NHS and private work although he does not undertake work in private practice. He declared two non-personal pecuniary interests: he was previously a primary investigator in the UK Glaucoma Treatment Study (UKGTS), a RCT of treatment for early glaucoma vs placebo. Funding for this study came through Moorfields Eye Hospital R&D department but originally was a grant from a drug company. In May 2007, he resigned as a PI at the study steering group meeting. Additionally he was previously a member of a research group investigating opacification of a particular lens implant (Hydroview H60M) used for cataract surgery. A grant from the lens manufacturer (Bausch & Lomb) now supports work looking into the extent and nature of this problem with recall of the patients who received this lens implant in Bristol. In May 2007, he resigned as an investigator on this study. He declared no personal family interests or personal non-pecuniary interests.
Second GDG Meeting (25th June 2007)	No change to declarations
Third GDG Meeting (26th July 2007)	No change to declarations
Fourth GDG Meeting (11th September 2007)	No change to declarations
Fifth GDG Meeting (24th October 2007)	No change to declarations
Sixth GDG Meeting (5th December 2007)	He did not attend this meeting.
Seventh GDG Meeting (29th January 2008)	No change to declarations
Eight GDG Meeting (13th March 2008)	No change to declarations
Ninth GDG Meeting (25th April 2008)	No change to declarations
Tenth GDG Meeting (19th May 2008)	No change to declarations
Eleventh GDG Meeting (3rd June 2008)	No change to declarations
Twelfth GDG Meeting (9th July 2008)	No change to declarations
Thirteenth GDG Meeting (31st July 2008)	No change to declarations

1.2.8 Mr Paul Spry

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	<p>He declared the following personal pecuniary interests: he owns shares in Healthcare Locums. He is also Editor-in-chief of the Optometric Glaucoma Society E-Journal, the production of which is sponsored by Pfizer. He is Chair of the College of Optometrists Glaucoma Panel.</p> <p>He declared a personal family interest: his wife works for Somerset PCT as a pharmacist medicines manager.</p> <p>He declared a non-personal pecuniary interest: he is a member of the steering committee for the United Kingdom Glaucoma treatment study. This study is funded by Pfizer.</p> <p>He declared no personal non-pecuniary interests.</p>
Second GDG Meeting (25th June 2007)	He did not attend this meeting.
Third GDG Meeting (26th July 2007)	He did not attend this meeting.
Fourth GDG Meeting (11th September 2007)	He did not attend this meeting.
Fifth GDG Meeting (24th October 2007)	No change to declarations
Sixth GDG Meeting (5th December 2007)	No change to declarations
Seventh GDG Meeting (29th January 2008)	No change to declarations
Eight GDG Meeting (13th March 2008)	No change to declarations
Ninth GDG Meeting (25th April 2008)	<p>The declarations above plus:</p> <p>He declared two personal pecuniary interests: he works for New Medica which is an extended contractor for glaucoma care to NHS. He also received expenses for accommodation and transport costs to a conference on shared care from Allergan. His honorarium was donated to the Bristol Eye Hospital charitable trust.</p>
Tenth GDG Meeting (19th May 2008)	No change to declarations
Eleventh GDG Meeting (3rd June 2008)	No change to declarations
Twelfth GDG Meeting (9th July 2008)	No change to declarations
Thirteenth GDG Meeting (31st July 2008)	No change to declarations

1.2.9 Mr Chris Steele

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	He declared a personal pecuniary interest: he is an NHS employee caring for glaucoma patients. He declared no personal family interest, non-personal pecuniary interest or personal non-pecuniary interest.
Second GDG Meeting (25th June 2007)	No change to declarations
Third GDG Meeting (26th July 2007)	No change to declarations
Fourth GDG Meeting (11th September 2007)	No change to declarations
Fifth GDG Meeting (24th October 2007)	No change to declarations
Sixth GDG Meeting (5th December 2007)	No change to declarations
Seventh GDG Meeting (29th January 2008)	No change to declarations
Eight GDG Meeting (13th March 2008)	He did not attend this meeting.
Ninth GDG Meeting (25th April 2008)	No change to declarations
Tenth GDG Meeting (19th May 2008)	No change to declarations
Eleventh GDG Meeting (3rd June 2008)	No change to declarations
Twelfth GDG Meeting (9th July 2008)	No change to declarations
Thirteenth GDG Meeting (31st July 2008)	He did not attend this meeting.

1.2.10 Ms Sheila Urquhart

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	She declared a personal pecuniary interest: she was employed by Peterborough PCT as Clinical Governance Optometry Lead. She declared no personal family interest, non-personal pecuniary interest or personal non-pecuniary interest.
Second GDG Meeting (25th June 2007)	No change to declarations
Third GDG Meeting (26th July 2007)	No change to declarations
Fourth GDG Meeting (11th September 2007)	No change to declarations
Fifth GDG Meeting (24th October 2007)	No change to declarations
Sixth GDG Meeting (5th December 2007)	No change to declarations
Seventh GDG Meeting (29th January 2008)	No change to declarations
Eight GDG Meeting (13th March 2008)	She did not attend this meeting.
Ninth GDG Meeting (25th April 2008)	No change to declarations
Tenth GDG Meeting (19th May 2008)	She declared that her personal pecuniary interest had expired: she is no longer Clinical Governance Optometry Lead for Peterborough PCT and so did not receive PCT funding after 30 th April 2008
Eleventh GDG Meeting (3rd June 2008)	No change to declarations
Twelfth GDG Meeting (9th July 2008)	No change to declarations
Thirteenth GDG Meeting (31st July 2008)	No change to declarations

1.2.11 Mr Richard Wormald

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	He declared a personal pecuniary interest: he is an NHS employee caring for glaucoma patients. He also undertakes work in private practice. He declared a non-personal non-pecuniary interest: he is on the steering committee for the UK Glaucoma Treatment Trial which is a study sponsored by Pfizer.
Second GDG Meeting (25th June 2007)	No change to declarations
Third GDG Meeting (26th July 2007)	The declarations above plus: He declared a personal non-pecuniary interest: he has been asked to speak at the Closed Meeting of the European Glaucoma Society on the deliberations of the NICE GDG
Fourth GDG Meeting (11th September 2007)	The declarations above plus: He declared a personal pecuniary interest: he received a fee from Merck Sharp and Dohme for £400 for running Saturday workshop on research methods for residents. He declared two non-personal pecuniary interests: He is investigator for the UK Glaucoma Treatment Trial and co-investigator for a compliance study at St Georges both of which are funded by Pfizer. He declared a personal non-pecuniary interest: he was invited to join the UK Glaucoma Alliance.
Fifth GDG Meeting (24th October 2007)	The declarations above plus: He declared a personal pecuniary interest: he received accommodation and travel expenses for a meeting in Durham on glaucoma funded by Alcon.
Sixth GDG Meeting (5th December 2007)	No change to declarations
Seventh GDG Meeting (29th January 2008)	The declarations above plus: He declared a personal pecuniary interest: he spoke at a Merck Sharp and Dohme funded meeting and donated his fees to glaucoma department at Moorfields Eye Hospital.
Eight GDG Meeting (13th March 2008)	No change to declarations
Ninth GDG Meeting (25th April 2008)	No change to declarations
Tenth GDG Meeting (19th May 2008)	He declared a personal pecuniary interest, expenses and honorarium for visit to University of Ottawa a visiting professor.
Eleventh GDG Meeting (3rd June 2008)	He did not attend this meeting.
Twelfth GDG Meeting (9th July 2008)	No change to declarations
Thirteenth GDG Meeting (31st July 2008)	The declarations above plus: He declared a personal pecuniary interest: he is chairing a clinical trials workshop in September 2008 which is sponsored by ACCO who in turn is funded by Allergan, his travel and accommodation expenses will be paid for.

1.2.12 Mr David Wright

GDG meeting	Declaration of Interests
First GDG meeting (4th June 2007)	He declared two personal pecuniary interests: as well as being a salaried employee of the International Glaucoma Association he is paid honoraria from Allergan, Pfizer, Alcon and Merck Sharp and Dohme, on an occasional basis for giving independent patients' perspective presentations. He declared a non-personal pecuniary interest: the International Glaucoma Association, his employer, receives funding for publications from Allergan, Alcon and Pfizer. Allergan has part funded a nurse employed by the IGA. He declared a personal non-pecuniary interest: he is a member of the UK Glaucoma Alliance, World Patient Association Eye Health programme. He declared no personal family interests.
Second GDG Meeting (25th June 2007)	No change to declarations
Third GDG Meeting (26th July 2007)	He did not attend this meeting.
Fourth GDG Meeting (11th September 2007)	No change to declarations
Fifth GDG Meeting (24th October 2007)	The declarations above plus: He declared a non-personal pecuniary interest: he received an honorarium worth £1500 from Pfizer for the All Eyes on Glaucoma Programme.
Sixth GDG Meeting (5th December 2007)	No change to declarations
Seventh GDG Meeting (29th January 2008)	He did not attend this meeting.
Eight GDG Meeting (13th March 2008)	He did not attend this meeting.
Ninth GDG Meeting (25th April 2008)	No change to declarations
Tenth GDG Meeting (19th May 2008)	No change to declarations
Eleventh GDG Meeting (3rd June 2008)	No change to declarations
Twelfth GDG Meeting (9th July 2008)	No change to declarations
Thirteenth GDG Meeting (31st July 2008)	No change to declarations

1.3 Declarations of interests of the NCC-AC members

GDG meeting	Declaration of Interests of the NCC-AC members
First GDG meeting (4th June 2007)	None
Second GDG Meeting (25th June 2007)	None
Third GDG Meeting (26th July 2007)	None
Fourth GDG Meeting (11th September 2007)	None
Fifth GDG Meeting (24th October 2007)	None
Sixth GDG Meeting (5th December 2007)	None
Seventh GDG Meeting (29th January 2008)	None
Eight GDG Meeting (13th March 2008)	None
Ninth GDG Meeting (25th April 2008)	None
Tenth GDG Meeting (19th May 2008)	None
Eleventh GDG Meeting (3rd June 2008)	None
Twelfth GDG Meeting (9th July 2008)	None
Thirteenth GDG Meeting (31st July 2008)	None

Appendix C

Search Strategies

Overview of Search Strategies

Searches were constructed by using the groups of terms listed below. These groups are expanded in full in the section on **Search Terms** following this.

Clinical searches were conducted in the following databases: Medline and Embase for all searches; The Cochrane Library (Central Register of Controlled Trials) for all searches excluding adverse events, risk factors and progression searches; Cinahl excluding laser and surgical treatments, additionally we did not have access to Cinahl when we ran the gonioscopy search; PsychINFO for patient education and information for patients; AMED (Allied and Complementary Medicine Database) for the complementary and alternative interventions; The Cochrane Database of Systematic Reviews and the Health Technology Assessment Database were searched for anything relating to glaucoma.

Economic searches were conducted in Medline, Embase, NHS EED (NHS Economic Evaluation Database) and HEED (Health Economic Evaluations Database). The HTA (Health Technology Assessment) database was also searched.

Evidence Table 1 Diagnostic accuracy of non-contact tonometry vs. Goldmann contact tonometry

Study details	Patients	Diagnostic tools	Measure of Disorders	Results	Comments	
Atkinson et al, 1992 ⁵ Study design: Diagnostic Evidence level: II	Patient group: Patients from general ophthalmology outpatients departments and glaucoma clinics across 3 UK centres. (type of glaucoma not specified) Exclusion criteria: Uncooperative patients or those with scarred corneas All patients N: 403 eyes Age (median): NR M/F: NR Drop outs: NR	Assessment tool under investigation: Pulse air non-contact tonometry* measured before Goldmann tonometry. Three different machines: <ul style="list-style-type: none"> • Machines A and B (same hospital) used at least 3 readings until 3 readings lay within 5mmHg of each other • Machine C (different centre) used 4 successive readings. If any reading >30mmHg a further set was taken with machine set to 30+ mode. Gold standard: Goldmann applanation tonometry (GAT) (calibrated Haag-Streit AG Goldmann tonometer. <ul style="list-style-type: none"> • Measured within 3 minutes of pulse air reading. Patients did not move from position between measurement and instillation of oxybuprocaine 0.4% & fluorescein. 	Machine A (64 eyes) † Sensitivity 81% Specificity 93% Positive predictive value 85% Negative predictive value 93% Prevalence 31% Positive Likelihood Ratio 12.47 Negative Likelihood Ratio 0.16 Pre-test odds 0.45 Post-Test Odds (Probability) +ve result 5.67 (85%) Post-Test Probability -ve result 5.28 (84%)	Results 81% 93% 85% 93% 31% 12.47 0.16 0.45 5.67 (85%) 5.28 (84%)	Funding: Not reported Limitations: Number of eyes were recruited was reported but not the number of patients. Appendix F

1 Cost-effectiveness analysis

1.1 Introduction

Most of the economic evidence of this guideline derives from original cost-effectiveness analyses carried out by the NCC-AC. The main cost-effectiveness analysis was carried out to answer the clinical questions on treatment of patients with OHT and COAG suspects (Chapter 7), and the clinical question on treatment of patients with COAG (Chapter 8). Throughout the guideline we refer to this analysis as ‘NCC-AC model’.

A further cost analysis was carried out to answer the clinical questions on diagnosis and monitoring measurements (Chapters 4 and 5). Throughout the guideline we refer to this analysis as ‘NCC-AC cost analysis’.

1.2 Methods

The GDG identified the initial treatment strategy for both COAG and OHT patients as a high priority area for economic analysis. Specifically, the aim was to determine the most cost-effective strategy for patients who have not been treated before. Therefore, the priority for economic evaluation was limited to the following interventions according to the availability of good data on their clinical effectiveness, current use and licensing as a first-choice treatment:

- no treatment
- medical treatment with prostaglandin analogues (PGA)
- medical treatment with beta-blockers (BB)
- trabeculectomy (for COAG patients only)

For this area a review of the literature was conducted followed by economic modelling of the cost-effectiveness of the listed interventions in England and Wales (1.3). The literature search and review methods can be found in 2.4 and 2.6.

The questions on clinical measurements at diagnosis and monitoring were assigned a medium priority for economic analysis and so only a simple cost-analysis (1.4) was performed.

1.3 NCC-AC model: Cost-effectiveness of treatment

Our aim in constructing the model was to determine the most cost-effective strategy in managing OHT and COAG patients from the point of diagnosis.

We found a number of economic evaluations in the published literature (Chapters 7 and 8) but still it was necessary to develop our own analysis to determine the most cost-effective treatment strategy for different subgroups of patients. We took this approach because we found limited applicability in the published economic evaluations, mainly because the important long-term consequences (i.e. development of blindness) were ignored³, drugs were lumped together in a single medical treatment group^{3,80,144}, or important alternatives such as surgery were not considered⁸². Furthermore most of the published studies did not evaluate cost-effectiveness using the NICE reference case^{3,82}.

The medical interventions we compared in the model are those which are licensed to be used as first-line treatments (beta-blockers and prostaglandin analogues). For COAG patients, trabeculectomy was compared to beta-blockers and prostaglandin analogues.

The following general principles were adhered to:

- The GDG was consulted during the construction and interpretation of the model.
- When published data was not available we used expert opinion to populate the model.
- Model assumptions were reported fully and transparently.
- The results were subject to sensitivity analysis and limitations were discussed.
- We followed the methods of the NICE reference case¹⁰⁸. Therefore costs were calculated from a health services perspective. Health gain was measured in terms of quality-adjusted life-years (QALYs) gained. Both future costs and QALYs were discounted at 3.5%.
- The model employed a cost-effectiveness threshold of £20,000 per QALY gained.

1.3.1 General method

Glaucoma is a progressive disease where a patient's sight can deteriorate and never recover. The model is thus represented by a Markov model where patients cannot go back to previous stages. The cycle length was set at 2 months as this was thought to be the minimum time after which a change in treatment could occur. All the probabilities, costs and health utilities were converted in order to reflect the two-month values.

When defining the COAG stages we have used an adapted version of the Hodapp, Parrish and Anderson classification (Table 168). We have opted for this staging system as it allows us to use costs and utility values associated with different severity levels of COAG already present in the literature (see 1.3.11 and 1.3.14).

It was also used in previous glaucoma economic models^{14,80} and in the selected sources of probability of progression¹⁴.

Compared to the original staging system, we have collapsed the last two stages (severe COAG and blindness) as there was an overlap of their definitions and a lack of data of progression in the absence of treatment from severe COAG to blindness.

Table 1 - Staging classification in the model

COAG STAGE	MEAN DEFECT SCORE
No COAG (a)	No visual field defect
Early	-0.01 to -6.00 dB
Moderate	-6.01 to -12.00 dB
Advanced	-12.01 to -20.00
Severe Visual Impairment	-20.01 or worse

(a) Includes OHT patients

Patients diagnosed with OHT could be initially treated with a beta-blocker or a prostaglandin analogue or could be offered no treatment until they develop COAG (Figure 66).

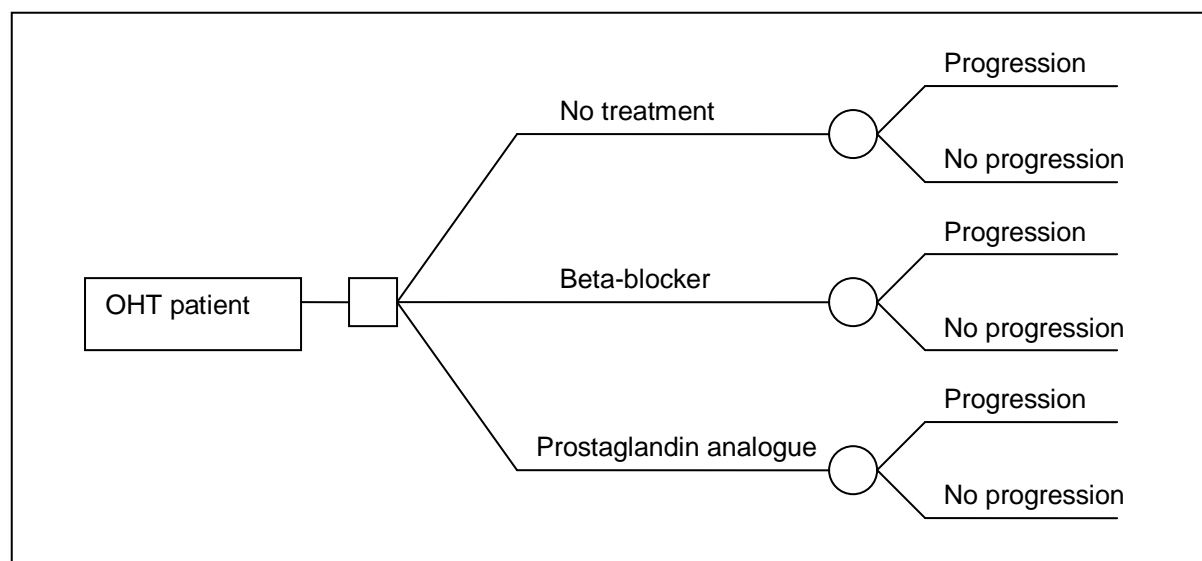

Figure 66 - Treatment strategies for OHT patients

Patients diagnosed with COAG could be treated either with a beta-blocker, a prostaglandin analogue, or trabeculectomy or could be offered no treatment until they progress to the following COAG stage (Figure 67). In the base case scenario patients were diagnosed with early COAG but in the sensitivity analysis we varied this assumption.

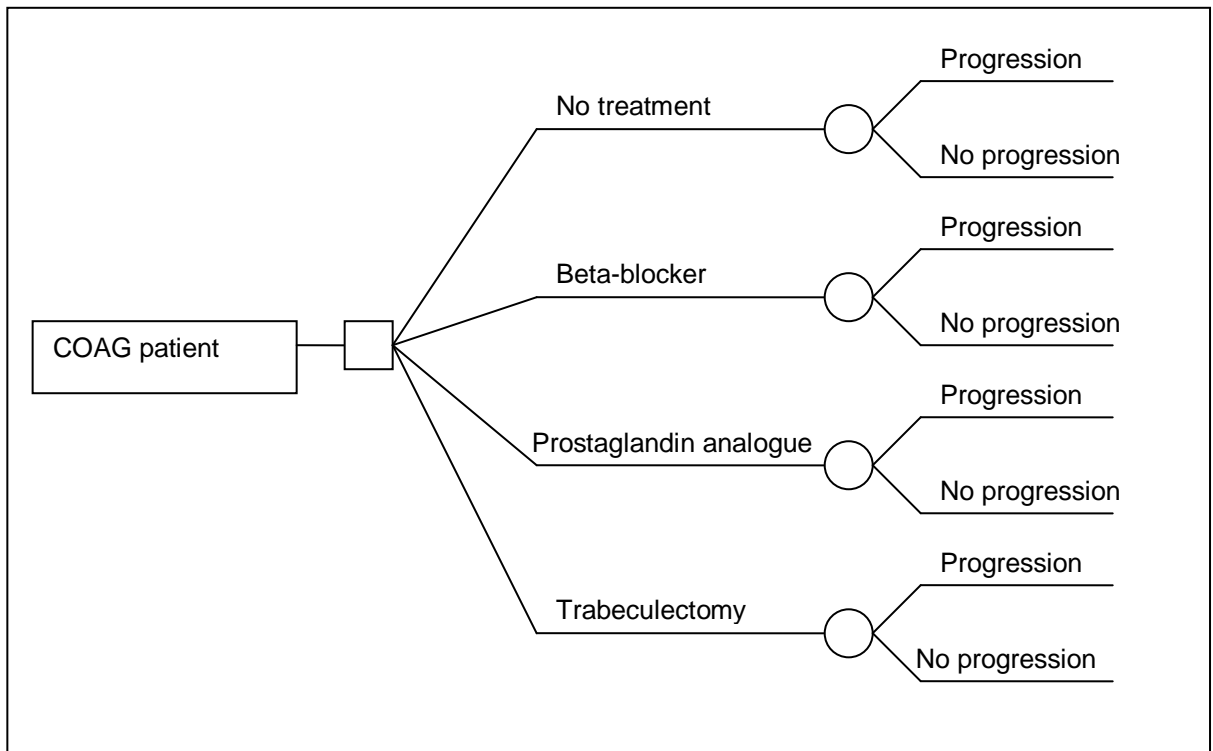

Figure 67 - Treatment strategies for COAG patients

The main effect of each strategy was considered to be the increase/decrease in risk of progression to the following COAG stages. However, in the literature the most commonly reported treatment outcome is the change in intraocular pressure (IOP). Two further systematic searches were conducted: one to find the Relative Risk (RR) of progression in OHT and in patients with COAG for each unit of IOP reduction (1.3.7), and the other one to find data on probability of progression from one stage to the next in both untreated and treated patients (1.3.5).

Each strategy is associated with upstream and downstream costs: the former are costs associated with the specific treatment while the latter are costs associated with the severity of the disease and thus dependent on the progression to later stages.

Some treatments could cause adverse events (see Chapters 7 and 8). Nevertheless not all of them result in important increased costs or reduced quality of life. We selected those more likely to occur and with a considerable impact on costs and quality of life using national sources³⁷ and expert opinion. Cataract and flat anterior chamber were the complications associated with trabeculectomy, while asthma was the only complication associated with beta-blockers for which incidence and annual cost per patient could be estimated. Other minor adverse events not requiring medical treatment are accounted for in the case of a change of COAG therapy.

For each strategy the expected healthcare costs and expected QALYs were calculated by estimating the costs and QALYs for each COAG stage and then multiplying them by the proportion of patients who would be in that stage as determined by the strategy taken.

We performed a probabilistic sensitivity analysis (PSA) to test the robustness of the results against the imprecision of these estimates and the other model parameters, and to obtain more accurate estimates of expected costs and QALYs.

In the base case of the OHT model, patients are 60 years old. However, from the review on risk of progression (see 1.3.5) we know that age is a significant risk factor for development of COAG. For this reason, we conducted a one-way sensitivity analysis on the age at decision point.

1.3.2 Time horizon

We considered the cost of treatment and health effects during a lifetime.

1.3.3 Key assumptions

In both COAG and OHT models the following assumptions were made:

- a) In the absence of treatment, the change in IOP is equal to 0.
- b) The change in IOP due to a treatment does not depend on whether the patient has COAG or OHT.
- c) A patient starting with a prostaglandin analogue who demonstrates intolerance to this drug is switched to a beta-blocker.
- d) A patient starting with a beta-blocker who demonstrates intolerance to this drug (including development of asthma) is switched to a prostaglandin analogue.
- e) After a first switch in treatment, a second one can occur only after progression and thus its cost is included in the downstream cost of the stage.
- f) When used after a treatment switch, beta-blockers and prostaglandin analogues have the same IOP lowering effect as when they are used as a first-choice treatment.
- g) The severity of the condition is similar in both eyes of a patient.

In the COAG model the following assumptions were made:

- a) In the base case the average age of patients at the beginning of the model is 72 years, as this was the mean age of COAG patients in the UK¹⁵⁴.
- b) Patients are reviewed every three months.
- c) The surgical procedure is trabeculectomy with or without enhancement.
- d) Trabeculectomy is performed first in one eye then in the other after 2 months.
- e) If post-surgery complications occur, the patient is treated appropriately and trabeculectomy is performed on the second eye if this has not already been done.

In the OHT model the following assumptions were made:

- a) In the base case the average age of patients at the beginning of the model is 60 years, being the mid-point of the range 40-80 for which data on progression is available.
- b) Untreated patients are reviewed on average every six months.
- c) Treated patients are reviewed on average every three months.

1.3.4 Software

The cost-effectiveness analysis was conducted using TreeAge Pro 2007.

1.3.5 Baseline probability of progression

A search was conducted to identify papers looking at progression in OHT and COAG. We selected papers which reported the probability for one or more of the following progressions:

- from OHT to COAG in untreated patients
- from Early to Moderate COAG in treated and untreated patients
- from Moderate to Advanced COAG in treated and untreated patients
- from Advanced COAG to Severe Visual Impairment in treated and untreated patients

Only studies using a definite staging system and published after 1998 were included since it was GDG opinion that before that time the detection of COAG was not accurate. We found three studies in total matching our inclusion criteria:

Lee et al (2006)⁸⁵ is a retrospective cohort study where patients in OHT and COAG stages were followed up for 5 years to detect progression. It was excluded due to its small sample size (on average 25 patients in each stage) and short follow-up.

A cost-effectiveness study⁸⁰ reported the annual risk of developing COAG in untreated OHT patients based on the results of the Ocular Hypertension Treatment Study⁵⁰, a multicentre RCT with 1636 participants randomised to either treatment or no treatment and followed-up for a mean of 6 years. In addition to the estimate of probability of progression in the absence of treatment, the study⁵⁰ calculated the hazard ratio of each clinical parameter for developing COAG through a multivariate Cox proportional hazards model.

A Health Technology Assessment (HTA)¹⁴ estimated the progression rates by COAG stage defined as mild, moderate and severe COAG, corresponding to our definitions of early, moderate and advanced COAG. The approach adopted was to use RCTs of treatment compared to control to calculate the progression rate by visual field mean defect. Since no RCT was found for the severe stage, its progression was projected from the previous stages.

Table 169 summarises the studies selected and their results.

Table 2 – Baseline probability of progressions

	Annual Probability Of Progression In Treated Patients	Annual Probability Of Progression In Untreated Patients	Source
OHT to COAG	-	2.2% (a)	Ocular Hypertension Treatment Study ^{50,80}
Early to Moderate COAG	20%	25%	HTA – Burr (2007) ¹⁴
Moderate to Advanced COAG	7%	11%	HTA – Burr (2007) ¹⁴
Advanced COAG to Severe Visual Impairment	6%	10%	HTA – Burr (2007) ¹⁴

(a) Average value. See Table 170 and Table 171 for all the combinations of risk factors.

The calculation of the probability of conversion from OHT to COAG was based on different combinations of those parameters that resulted in significant risk factors for the progression from OHT to COAG. Following the exclusion of pattern standard deviation and cup-disc ratio since they are already clinical signs of COAG, the significant risk factors identified were age, IOP and central corneal thickness (CCT). First we inputted the probability of progression for each age group in the model (Table 170), and then we multiplied this by the RR resulting from the combination of IOP and CCT (Table 171) as follows:

$$I \quad pCOAG = pCOAG[age] \times RR$$

Table 3 - Probability of developing COAG in OHT patients (a)

Age group	Annual probability of progression in untreated patients
40-49 years	1.50%
50-59 years	1.90%
60-69 years	2.27%
70-80 years	2.69%

(a) Source: Kymes et al (2006)⁸⁰

Table 4 - Relative risk for progression to COAG in OHT patients (a)

IOP	CCT	RR
>21 – 25 mmHg	>590 μm	0.16
>25 – 32 mmHg	>590 μm	0.49
>21 – 25 mmHg	555-590 μm	0.73
>25 – 32 mmHg	555-590 μm	1.06
>21 – 25 mmHg	≤ 555 μm	1.39
>25 – 32 mmHg	≤ 555 μm	2.93

(a) Source: Gordon et al (2002)⁵⁰

The original IOP categories reported in the study⁵⁰ were IOP >21 - 23.75 mmHg, IOP 23.75-25.75 mmHg, and IOP 25.75 - 32 mmHg. The GDG felt that keeping the middle group was clinically meaningless as the range limits are so close; therefore we incorporated this group into the two remaining groups IOP >21 – 25 mmHg and IOP >25 – 32 mmHg. The CCT categories in the study were CCT>588 μm , CCT 555-588 μm , and CCT ≤ 555 μm , which for clinical simplicity were rounded to CCT>590 μm , CCT 555-590 μm , and CCT ≤ 555 μm .

1.3.6 IOP reduction

Data on change in IOP from baseline due to each treatment was derived from the systematic review of clinical effectiveness of treatments in OHT and COAG patients (Chapter 7 and 8). No studies comparing prostaglandin analogues to no treatment and trabeculectomy to no treatment met the inclusion criteria. The data used in the model is summarised in Table 172 and correspond to the results of the forest plots in Figure 5, Figure 10, and Figure 44 in Appendix E. Among the comparisons of trabeculectomy with any medical treatment, the Collaborative Initial Glaucoma Treatment Study (2001)⁸⁹ was the only study comparing beta-blockers to trabeculectomy and thus the only trial included for this specific comparison (Figure 44 – subgroup 2).

Table 5 – Mean difference in change in IOP from baseline

	Mean difference
Beta-blockers vs No treatment	- 2.88 mmHg
Prostaglandin analogues vs Beta-blockers	- 1.32 mmHg
Trabeculectomy vs Beta-blockers	- 3.6 mmHg

1.3.7 IOP reduction and progression

We conducted a search in order to find a measure of the link between IOP reduction and protection against progression. Two scenarios were considered:

- a link between IOP reduction and reduced conversion from OHT to COAG,
- a link between IOP reduction and reduced progression of established COAG.

We included only studies reporting the RR of each mmHg reduction in IOP for progression or conversion, defined by deterioration in visual field or optic nerve appearance or both.

We found a study reporting the RR of developing COAG from OHT per unit of IOP reduction⁵⁰ and two studies reporting the RR of progression in COAG patients per unit of IOP reduction^{86,87}. Leske et al (2007)⁸⁷, an update of Leske et al (2003)⁸⁶, is more up to date, and more conservative and so we used this in the base-case model.

In OHT patients, the percentage reduction in the probability of developing COAG was 10% per mmHg of IOP reduction. In COAG patients, the percentage reduction in the probability of progressing was 8% per mmHg of IOP reduction.

The overall effectiveness of each intervention was calculated by multiplying the mean difference in IOP reduction with the percentage reduction in progression per mmHg of IOP reduction.

Table 6 – Overall Effectiveness of interventions

INTERVENTION	MEAN CHANGE IN IOP (mmHg)	PROGRESSION REDUCTION per mmHg change in IOP		PROGRESSION REDUCTION (overall effectiveness)	
		OHT	COAG	OHT	COAG
No treatment	0	10%	8%	0	0
Beta-blockers	2.88	10%	8%	29%	23%
Prostaglandin analogues	4.2	10%	8%	42%	34%
Trabeculectomy	6.48	NA	8%	NA	52%

1.3.8 Probability of progression after treatment

In each branch of the model where patients received a treatment, the baseline probability of progression in the absence of treatment was adjusted by the overall effectiveness of the respective treatment:

II Baseline probability * (1-overall effectiveness)

For example, a patient with Early COAG would have an annual probability of progression to Moderate COAG of 25% if untreated, and $25\% * (100\% - 34\%) = 16.5\%$ if treated with a prostaglandin analogue.

The probability thus calculated was used for the time during which the patients received that treatment in the model. Once a switch in treatment occurred without progression this probability was recalculated according to the new drug used. Once a patient has progressed to the following stage, the new probability is the baseline probability in treated patients for that stage (Table 169). The rationale is that after progression any new treatment could be introduced, for which we cannot estimate the effectiveness. As a consequence, we used progression estimates for nonspecific treatments.

1.3.9 Other probabilities

Other probabilities used in the model were:

- Probability of developing asthma after use of beta-blockers: it was estimated from a prospective cohort study⁷⁴ comparing the difference in respiratory disease in 2,645 patients treated with beta-blockers to 9,094 unexposed patients. The difference between the proportions of patients given a new prescription of drug for reversible airways obstruction in 12 months after treatment was 3.3%. The same study⁷⁴ reports that the risk of respiratory problems ceases to be significant after the first year of exposure; therefore the probability of developing asthma is kept in the model only within the first year.

- Probability of discontinuation due to reasons other than treatment failure: we found one UK study¹⁶⁶ reporting the proportion of patients discontinuing treatment for reasons other than treatment failure (i.e. adverse events, intolerance). In this study, 19 out of 149 patients (13%) treated with prostaglandin analogues and 158 out of 632 patients (25%) treated with beta-blockers discontinued within 1 year. From the latter figure we subtracted 3.3% which was the proportion of patients developing asthma that would have been included in the discontinuation of beta-blockers; the remaining annual probability for this group is 21.7%. Data for later years were not available; thus these probabilities were used only during the first year of treatment.

- Probability of post-surgery complications: the GDG identified those complications that require further treatment and are therefore associated with extra costs. Rare (with an incidence of 1% or less) and promptly resolving complications were excluded. Cataract and flat anterior chamber were the two complications identified. There was overall agreement between experts' estimates and national sources on the incidence of cataract. The probability was obtained from the National Survey of Trabeculectomy³⁷ considering only the cases that required cataract extraction (2.5%). The incidence of flat anterior chamber requiring treatment was estimated by experts as 0.75%, reported in the National Survey³⁷ as 0.2%, and in the Moorfields Glaucoma service annual audits 2001-2007 as 4%. We decided to use an average of these figures (1.65%) to estimate the probability of reformation of anterior chamber. Cataract extraction and reformation of anterior chamber were assumed to occur in the model only in the two months (1 cycle) following surgery for both the first eye and the second eye operation.

- Probability of needing medication after surgery: the probability of adding a medication because of poor IOP control after trabeculectomy was obtained from the National Survey of Trabeculectomy³⁸. Patients requiring post-operative anti-glaucoma medications were 147/1105 (13.3%) after 1 year. This probability was also used in the following years.

1.3.10 Life expectancy

Life expectancy in patients with COAG or OHT was assumed to be the same as the general population in England and Wales. Life expectancy was estimated for each age by calculating the mean of the figures for men and women reported in the Life Tables for the general population of England and Wales in the year 2004-2006 in the Government Actuary Department (http://www.gad.gov.uk/Demography_Data/Life_Tables/Interim_life_tables.asp)

1.3.11 Quality of life

The utility scores in Table 174 are a measure of the quality of life associated with each of the COAG stage on a scale from 0 (death) to 1 (perfect health). A systematic search for quality of life in OHT and COAG patients was performed. Studies were included if health state utility values were reported or obtainable for stages separately and they were based on visual field defect.

One study¹¹⁹, using data obtained from Brown et al (2003)¹², was selected that applied utilities for visual acuity to each category of visual field loss. Two functions to calculate health utilities for each continuous dB increment of visual field defect were developed. In order not to favour the most effective treatment, we adopted the formula that resulted in the most conservative estimate of quality of life detriment resulting from visual field defects:

$$\text{III Health utility} = 0.98991 + 0.0022 * \text{dBs} - 0.00080518 * \text{dBs}^2$$

where dBs are expressed as an absolute numbers and is therefore a positive number.

Since the stages in the model were defined as ranges of visual field defect (Table 168), it was possible to calculate the upper and lower limits and the central utility score for each stage by substituting the range limits and the central value of the stage definition. The central value of the severe visual impairment stage was assumed to be -26dB following the World Health Organization definition of blindness as reported in Rein et al (2007)¹¹⁹, while the upper limit was assumed to be -30dB. The quality of life in OHT patients was assumed to be equal to perfect health as there was no visual field defect.

Table 7 - Health Utilities by COAG stage

STAGE	LOWER LIMIT	UPPER LIMIT	CENTRAL VALUE
OHT	-	-	1
Early COAG	0.974	0.990	0.989
Moderate COAG	0.900	0.974	0.944
Advanced COAG	0.712	0.900	0.819
Severe Visual Impairment	0.331	0.712	0.503

When we compared our estimates with other published studies^{16,53,78,84} we found that overall we had been more conservative.

Adverse events were assumed to be negligible in terms of quality of life because they could be promptly treated, with the exception of asthma. A search for quality of life measures in the CEA Registry (<https://research.tufts-nemc.org/cear/default.aspx>) retrieved a study¹³⁰ where the health utility in treated asthma patients was 0.84. Hence it was assumed that treated asthma symptoms produce a decrease in quality of life of 0.16 over one year. This is probably an overestimation because the treatment with beta-blockers should be immediately discontinued with the consequent reduction of symptoms. On the other hand, beta-blockers are known to have other important adverse events for which incidence, costs and quality of life detriment could not be estimated.

1.3.12 Calculating QALYs gained

For each strategy, the expected QALYs per cohort of patients in each cycle are calculated as follows:

$$\text{IV Expected QALYs} = U_{\text{OHT}} \times P_{\text{OHT}} + U_e \times P_e + U_m \times P_m + U_a \times P_a + U_b \times P_b + P_{\text{ast}} \times U_{\text{ast}}$$

where

$U_{\text{OHT}}, U_e, U_m, U_a, U_b$ = the utility score for each stage

U_{ast} = the utility detriment due to asthma (negative number)

$P_{\text{OHT}}, P_e, P_m, P_a, P_b$ = the proportion of patients in each of the COAG stage at the end of each cycle

P_{ast} = the proportion of patients developing asthma in each cycle

The proportion of patients in each COAG stage depends on the progression reduction of the treatment and on the proportion of patients still alive according to the mortality rate for the general population of England and Wales.

The overall lifetime expected QALYs are given by the sum of QALYs calculated for each cycle. The incremental QALYs gained associated with a treatment strategy are calculated as the difference between the expected QALYs with that strategy and the expected QALYs with the comparator.

1.3.13 Upstream treatment costs

Upstream treatment costs are those directly associated with the treatment strategy considered and so those arising before a progression. The resources used in each cycle for the different strategies are summarised in Table 175. These resources are used only until the patient remains in the treatment strategy assigned at the beginning of the model. Patients in the beta-blocker and prostaglandin analogue arms can interchange treatment in which case the cost of an additional visit is added and the cycle cost is calculated according to the new treatment.

Table 8 - Resources used

	No Treatment	Beta-blockers	Prostaglandin analogues	Surgery	Source
Drugs	-	2 bottles of Timolol	2 bottles of either Latanprost, Travoprost, Bimatoprost	Used post-operatively: 1 bottle Chloramphenicol + 4 bottles Predforte + 1 bottle Cyclopentolate 1 bottle of either a prostaglandin or a beta-blocker in the two months between surgery in first eye and second eye	Expert opinion
Trabeculectomy inpatient	-	-	-	34% in both first and second cycle (first and second eye)	Hospital Episode Statistics for 2006/07
Trabeculectomy daycase	-	-	-	66% in both first and second cycle (first and second eye)	Hospital Episode Statistics for 2006/07
Monitoring visits - OHT	0.33 (a)	0.33 (a) + 1 if treatment switch	0.33 (a) + 1 if treatment switch	0.33 (a)	Expert opinion and recommendation in the Guideline
Monitoring visits - COAG	0.67 (b)	0.67 b + 1 if treatment switch	0.67 b + 1 if treatment switch	0.67 (b)	Expert opinion and recommendation in the Guideline

(a) .One visit every 6 months

(b) One visit every 3 months

The costs of the resources used are reported in Table 176. All the cost figures are expressed in 2006 Pound Sterling.

Table 9 - Cost per unit of resource used

	COST	SOURCE
Bottle of beta-blocker	£3.12	BNF 56
Bottle of prostaglandin analogue	£11.70 (a)	BNF 56
Post-operative drug treatment	£9.7 (b)	BNF 56
Trabeculectomy – inpatient	£1,316	National Schedule of Reference Costs 2006-07 for NHS Trust & PCT Combined (HRG code BZ18Z)
Trabeculectomy – daycase	£789	National Schedule of Reference Costs 2006-07 for NHS Trust & PCT Combined (HRG code BZ18Z)
Trabeculectomy – weighted average cost	£968 (c)	NCC-AC calculation
Cost of monitoring visit	£62	National Schedule of Reference Costs 2006-07 for NHS Trust & PCT Combined – Consultant led follow up attendance outpatient face to face - specialty code 130 Ophthalmology

(a) Mean cost of Travoprost, Latanoprost and Bimatoprost

(b) Cost of 1 Chloramphenicol + 4 Predforte + 1 Cyclopentolate (£2.72 + 4 x £1.50 + £0.97)

(c) Proportion of inpatient x cost inpatient + proportion daycase x cost daycase

1.3.14 Downstream treatment costs

While a calculation of the resources used was made for the upstream costs, it would have been inaccurate if not impossible to do that for the costs arising after a disease progression. We conducted a systematic search on the cost of glaucoma stages and we selected a cost-of-illness study¹⁵¹ reporting the direct healthcare cost per patient associated with each COAG stage. We chose this study because the staging system was the same that we adopted (Hodapp, Parrish and Anderson classification, 1.2), and it contained UK data. The figures in Table 177 were obtained by converting the 2004 Euros into GBP by a conversion factor of 0.67, which was the reciprocal of the one used by the author to convert GBP into Euros.

Table 10 – Annual cost of COAG stage per patient

Stage	Cost year per patient (£)	Source
Early COAG	399	Traverso et al (2006) ¹⁵¹
Moderate COAG	449	Traverso et al (2006) ¹⁵¹
Advanced COAG	357	Traverso et al (2006) ¹⁵¹

In the paper, the costs of severe COAG and blindness did not account for social costs, thus leading to an underestimation of the true costs. Therefore for the last stage (Severe Visual Impairment) we based our cost analysis on the services

provided to patients with blindness as described in Meads and Hyde (2003)⁹⁶. Table 178 illustrates the services considered in our analysis, the calculation of their costs, and the proportion of patients receiving each service as reported in Meads and Hyde (2003)⁹⁶. The same study includes the cost of depression and hip replacement in individuals with visual impairment. We did not use these data as they were not controlled for incidence in the general population.

Table 11 - Cost of severe visual impairment

Service	Cost (£)	Source	Proportion of patients receiving the service
Blind registration	122.78 (one-off)	Pay Circular 3/2008 – Annex A Section 5 http://www.nhsemployers.org/pay-conditions-pay-conditions-2339.cfm%20Pay%20circular%20M&D%20(3/2008)	95%
Low vision aids	150 (one-off)	Meads and Hyde (2003) ⁹⁶ – figures uplifted to year 2008	33%
Low vision rehabilitation	207 (one-off)	Curtis (2007) ²⁸ - NHS community occupational therapist cost of episode of care including qualification	11%
Community care	8,216	Curtis (2007) ²⁸ - Annual cost for a local authority home care worker	6%
Residential care	16,344	Curtis (2007) ²⁸ - Annual cost of private residential care assuming that 30% of residents pay themselves	30%

The cost of OHT was not used in the model because it is always dependent on the treatment strategy adopted (upstream cost).

For each strategy, the expected cost per cohort of patients in each cycle is calculated as follows:

$$V \text{ Expected cost} = UC_{\alpha} \times P_{\alpha} + \sum DC_i \times P_i$$

where

UC_{α} = upstream cost of the initial treatment strategy

P_{α} = proportion of patients in the initial treatment strategy

DC_i = downstream cost of stage i

P_i = proportion of patients in the stage i

and where stage i could be any later stage

The proportion of patients in each COAG stage depends on the magnitude of the progression reduction of the treatment and on the proportion of patients still alive according to the mortality rate for the general population of England and Wales.

The overall lifetime expected costs are given by the sum of costs calculated for each cycle. The incremental cost associated with a treatment strategy is calculated as the difference between the expected cost with that strategy and the expected cost with the comparator.

1.3.15 Adverse events and complications costs

Three main adverse events and complications were identified (1.3.9) and their costs estimated as shown in Table 179.

We searched for UK cost of illness studies on asthma. We found one study¹⁶⁰ but being too old we opted for a bottom-up approach. We estimated the cost of an annual treatment with beta-agonist and corticosteroids from a NICE Technology Appraisal¹¹.

The cost of treating the two post-operative complications, cataract and anterior flat chamber, corresponds to the cost of cataract extraction and anterior chamber reformation.

Table 12 - Cost of adverse events and complications

	COST	SOURCE
Annual cost of asthma treatment	£147 (a)	Brocklebank et al (2001) ¹¹
Cataract extraction	£977 (b)	National Schedule of Reference Costs 2006-07 for NHS Trust & PCT Combined – HRG code BZ03Z
Reformation of anterior chamber of eye	£974 (c)	National Schedule of Reference Costs 2006-07 for NHS Trust & PCT Combined – HRG code BZ19Z

(a) *annual cost of beta-agonist + corticosteroids = 105+42 = £147*

(b) *all daycase*

(c) *weighted cost - £556 x 46%(daycase) + £1,330 x 54%(inpatient)*

In addition, a treatment change following asthma is always associated with the one-off cost of an extra visit (£62).

1.3.16 Probabilistic sensitivity analysis

A probabilistic sensitivity analysis was performed to assess the robustness of the OHT and COAG models results to plausible variations in the model parameters.

Probability distributions were assigned to each model parameter, where there was some measure of parameter variability (Table 180). We then re-calculated the main results 10000 times, and each time all the model parameters were set simultaneously, selecting from the respective parameter distribution at random. When some distributions were used in either the OHT model or in the COAG model only, this is specified in Table 180.

Table 13 - Parameters used in the probabilistic sensitivity analysis (a)

Description of variable	Mean value	Probability distribution	Parameters	Source	Model
Mean difference in change in IOP from baseline – BB vs No Treatment	- 2.88 mmHg	Normal	SD = 0.643	Systematic review of clinical effectiveness	COAG and OHT models
Mean difference in change in IOP from baseline – PGA vs BB	-1.32 mmHg	Normal	SD = 0.24	Systematic review of clinical effectiveness	COAG and OHT models
Mean difference in change in IOP from baseline – trabeculectomy vs BB	-3.6 mmHg	Normal	SD = 0.418	Systematic review of clinical effectiveness	COAG model
Age at diagnosis of OHT	60 years	none		assumption	OHT model
Age at diagnosis of COAG	72 years	Custom distribution	age range/probability: 40-44 1.6% 45-49 2.3% 50-54 3.5% 55-59 5.4% 60-64 8.8% 65-69 13.4% 70-74 16.3% 75-79 18.5% 80-84 16.3% 85-89 13.9%	Tuck et al (1998) ¹⁵⁴	COAG model
Cost of Early COAG	£399	Gamma	$\alpha = 61.46$ $\lambda = 0.154$ based on +/-25% for upper and lower bounds	Traverso et al (2006) ¹⁵¹	OHT model
Cost of Moderate COAG	£449	Gamma	$\alpha = 61.46$ $\lambda = 0.137$ based on +/-25% for upper and lower bounds	Traverso et al (2006) ¹⁵¹	COAG and OHT models
Cost of Advanced COAG	£357	Gamma	$\alpha = 61.46$ $\lambda = 0.172$ based on +/-25% for upper and lower bounds	Traverso et al (2006) ¹⁵¹	COAG and OHT models
Cost of Severe Visual Impairment	see 1.3.14	none		NCC-AC calculation of cost of Severe Visual Impairment	COAG and OHT models

Cost of Blindness Registration	£122.78	Gamma	$\alpha = 61.46$ $\lambda = 0.500$ based on +/-25% for upper and lower bounds	Pay Circular 3/2008 – Annex A Section 5 http://www.nhsemployers.org/pay-conditions/pay-conditions-2339.cfm%20Pay%20circular%20M&D%20(3/2008)	COAG and OHT models
Cost of low-vision aids	£150	Gamma	$\alpha = 61.46$ $\lambda = 0.410$ based on +/-25% for upper and lower bounds	Meads and Hyde (2003) ⁹⁶	COAG and OHT models
Cost of low-vision rehabilitation	£207	Gamma	$\alpha = 61.46$ $\lambda = 0.297$ based on +/-25% for upper and lower bounds	Curtis (2007) ²⁸	COAG and OHT models
Cost of community care for blindness	8,216	Gamma	$\alpha = 61.46$ $\lambda = 0.007$ based on +/-25% for upper and lower bounds	Curtis (2007) ²⁸	COAG and OHT models
Cost of residential care for blindness	16,344	Gamma	$\alpha = 61.46$ $\lambda = 0.004$ based on +/-25% for upper and lower bounds	Curtis (2007) ²⁸	COAG and OHT models
Cost of beta-blockers	see Table 176	none		BNF 56	COAG and OHT models
Cost of prostaglandin analogues	see Table 176	none		BNF 56	COAG and OHT models

1.3.17 Results of the cost-effectiveness analysis

1.3.17.1 OHT

We found that the results of the OHT model were particularly sensitive to the age of patients at the decision point. Age is a risk factor for the development of COAG but it is also important for estimating the likelihood of visual impairment. Table 181 shows the results of the base case analysis and the one-way sensitivity analysis conducted by varying the patient's age between 40 and 80. Beyond these limits we do not have data on the probability of developing COAG.

For patients at an average age of 60, no treatment is the most cost-effective strategy if the CCT >555µm and IOP is within the 21 – 32 mmHg range. If the CCT ≤555 µm, treatment with prostaglandin analogues is the most cost-effective strategy for any IOP.

Table 14 - Results of OHT model – base case

	Mean cost (£)	QALYs	Incremental cost (£) per QALY gained vs No Treatment	Incremental cost (£) per QALY gained vs BB	One-way sensitivity analysis on age
IOP>21 – 25 mmHg, CCT>590 µm					
No Treatment	2,165	14.574	-	-	-
BB	4,748	14.586	213,504	-	Not sensitive to age
PGA	5,665	14.586	296,593	Dominated	Not sensitive to age
IOP >25 – 32 mmHg, CCT>590 µm					
No Treatment	2,872	14.471	-	-	-
BB	5,105	14.513	52,670	-	Not sensitive to age
PGA	5,934	14.522	59,805	94,182	Not sensitive to age
IOP>21 – 25 mmHg, CCT 555-590 µm					
No Treatment	3,344	14.403	-	-	-
BB	5,351	14.464	32,749	-	Not sensitive to age

IOP >25 – 32 mmHg, CCT 555-590 µm					
No Treatment	3,940	14.316	-	-	-
BB	5,672	14.399	20,864	-	If age<60 BB is more cost-effective than no treatment.
PGA	6,368	14.421	23,124	31,650	If age<58 PGA is more cost-effective than no treatment. PGA vs BB not sensitive to age.
IOP >21 – 25 mmHg, CCT ≤555 µm					
No Treatment	4,484	14.237	-	-	-
BB	5,974	14.339	14,617	-	If age>67 no treatment is more effective than BB.
PGA	6,603	14.367	16,307	22,464	If age>65, no treatment is more cost-effective than PGA. If age<58 PGA is more cost-effective than BB..
IOP >25 – 32 mmHg, CCT ≤555 µm					
No Treatment	6,475	13.949	-	-	-
BB	7,179	14.102	4,605	-	If age>80 no treatment is more effective than BB.
PGA	7,566	14.150	5,429	8,056	If age>77 BB are more cost-effective than PGA. If age >80 no treatment is more cost-effective than PGA.

The cost-effectiveness of treating OHT is strongly interconnected with the patient's risk factors for the development of COAG (age, IOP and CCT) and with the likelihood of becoming visually impaired which depends on the age at diagnosis.

In the absence of risk factors, the probability of developing COAG is so low that the little improvement in the quality of life treatment would bring does not warrant the high costs of a lifetime treatment. Not treating patients with IOP>21-25mmHg and CCT>590µm is significantly cost-effective compared to PGA as reported in Table 182, where the 95% confidence interval (CI) is above the £20,000/QALY threshold. When compared to BB, the cost-effectiveness is not significant as the lower limit crosses the £20,000/QALY threshold.

Medical treatment is cost-effective in patients with CCT≤555 µm with any IOP up to 32 mmHg and in patients with CCT 555-590 µm and IOP >25-32 mmHg. However, the 95% CI limits crossed our cost-effectiveness threshold (Table 182).

Considering only those patients for whom treatment is cost-effective, if both beta-blockers and prostaglandin analogues are available (e.g. they are not contraindicated), beta-blockers are more cost-effective if CCT 555-590 μm and IOP >25-32mmHg or if CCT<555 μm and IOP >21 – 25 mmHg while prostaglandin analogues are more cost-effective if CCT<555 μm and IOP >25 – 32mmHg. The results of the comparison between prostaglandin analogues and beta-blockers are not significant with 95% confidence (Table 182). For these groups of patients, there is an age beyond which treatment does not substantially improve the quality of life, and thus it is not cost-effective (see One-way sensitivity analysis in Table 181). For clinical simplicity, the results can be rearranged in order to round the age threshold and to limit the maximum number of age groups to two for each IOP and CCT combination. In this case after we exclude beta-blockers from the comparison, prostaglandin analogues are cost-effective up to the age of 65 in the IOP >21 – 25 mmHg and CCT<555 μm group and up to the age of 80 in the IOP >25 – 32 mmHg and CCT<555 μm group,

Table 15 - Results of PSA – OHT model

	Mean ICER (£/QALY)	95% CI – lower limit (£/QALY)	95% CI – upper limit (£/QALY)	Probability of being cost-effective at £20,000/QALY

1.3.17.2 COAG

Table 183 shows the results of the base case COAG model. Trabeculectomy is the most effective and most cost-effective option.

Table 16 - Results of COAG model – base case

	Mean cost (£)	QALYs	Incremental cost (£) per QALY gained vs No Treat	Incremental cost (£) per QALY gained vs BB	Incremental cost (£) per QALY gained vs PGA	Sensitivity analysis
No Treat	6,246	8.635	-	-	-	If annual probability of progression < 6% or surgical intervention costs >£1,455, trabeculectomy is not cost-effective anymore. Results not sensitive to COAG stage.
BB	6,017	8.714	cost saving	-	-	
PGA	6,113	8.745	cost saving	3,100	-	
Trab	7,247	8.849	14,679	9,113	10,906	

When the severity of the disease (COAG stage) was varied, the overall results did not change and trabeculectomy was still the most cost-effective strategy. Sensitive parameters in the model were the annual probability of progression to the following stage and the cost of trabeculectomy. When the probability of progression was lowered from 25% in the base case to 6%, trabeculectomy was not cost-effective anymore. By using the following formula we could calculate the rate in visual field deterioration corresponding to a 7% annual probability of progression:

$$\text{VI rate} = (\text{VF}_{\text{mod}} - \text{VF}_{\text{Early}}) / \text{years}$$

where

VF_{mod} = absolute value of lower bound of Moderate COAG definition (6.01 dB)

VF_{Early} = absolute central value of Early COAG definition (3.00)

years = years necessary to reach Moderate COAG, calculated as

$$\text{VII years} = 1 / (\text{probability of progression})$$

The rate thus calculated was

$$\text{VIII rate} = (6.01 - 3.00) / (1 / 0.06) = 0.18 \text{ dB/year}$$

If the visual field deteriorates at a rate lower than this value, trabeculectomy is not cost-effective.

The uncertainty over the cost-effectiveness of trabeculectomy was revealed by the results of the PSA as well (Table 184). While beta-blockers and prostaglandin analogues are significantly more cost-effective than no treatment (i.e. the upper limit is below the £20,000/QALY threshold used in our economic evaluation), the

upper limit of the ICER of trabeculectomy vs any other intervention always exceeds the £20,000/QALY threshold (Table 184).

Table 17 - Results of PSA - COAG model

	Mean ICER (£/QALY)	95% CI – lower limit (£/QALY)	95% CI – upper limit (£/QALY)	Probability of being cost-effective at £20,000/QALY
BB vs no treatment	cost saving	cost saving	9,461	No treatment 1% BB 4% PGA 38% Trab 57%
PGA vs no treatment	cost saving	cost saving	13,836	
Trab vs no treatment	3,488	cost saving	57,676	
PGA vs BB	3,079	cost saving	23,258	
Trab vs BB	7,483	cost saving	85,631	
Trab vs PGA	11,495	cost saving	122,050	

When the severity of COAG at the point of decision was increased to moderate or advanced, trabeculectomy became more cost-effective and this result less sensitive to the probability of progression. By applying a formula similar to VI, we estimated the minimum rate of visual field deterioration in order for trabeculectomy to be cost-effective in moderate COAG (0.09dB/year) and advanced COAG (0.08dB/year).

1.3.18 Discussion

The cost-effectiveness of treating OHT patients depends on their risk for development of COAG. We found that age, IOP and CCT are the clinical indicators correlated with this risk (1.3.5). According to the possible combinations of these parameters, different strategies can be cost-effective.

Beta-blockers are cost-effective for patients with IOP >25 – 32 mmHg and CCT 555 – 590 µm up to the age of 60. Prostaglandin analogues are cost-effective for patients with IOP > 21 – 25 mmHg and CCT <555 µm up to the age of 65 and for patients with IOP >25 – 32 mmHg and CCT ≤555µm up to the age of 80. All other OHT patients should not receive treatment according to our analysis.

On the other hand, treating all COAG patients from an early stage is cost-effective. Results show that trabeculectomy is the most cost-effective treatment. Nevertheless being an invasive procedure it has drawbacks that we could have failed to capture in our analysis. More generally, some treatments are associated with common adverse events and complications which often require further interventions. In our model we have tried to incorporate the costs and effects of the most common and serious ones but we might have underestimated them since there is no good up to date literature on this topic.

In addition, the cost-effectiveness of trabeculectomy is conditional upon a considerable rate of progression in visual field defect. It could be worthwhile initiating medical treatment while monitoring for progression; only when a progression is detected could the patient be listed for surgery.

For patients in the later stages of COAG trabeculectomy is cost-effective even in the presence of a very low rate of progression (see 1.3.17.2) because the threat to their vision is more imminent.

We have kept some parameters conservative:

- Quality of life estimates from the selected study were generally higher than in other excluded studies.
- Increase in mortality risk due to blindness or visual impairment was not included in the model.
- The probability of developing COAG in OHT patients 70-80 years old was used also for older patients, although it was likely to be higher.
- Normal Tension Glaucoma patients were included in the IOP reduction results as well. However, including data for this population could decrease the effectiveness of treatment in reducing IOP. In fact, the effectiveness corresponds to the difference between IOP at baseline and after treatment and since their IOP at baseline is already low and drugs could be less effective in decreasing this value further.

Had we modified these assumptions, we would have favoured the most effective interventions.

However, our analysis is limited for a number of reasons:

- The OHT model is based on the findings of an RCT⁵⁰ where patients were included only if their age was between 40 and 80 years and IOP between >21 and 32 mmHg. Therefore we cannot generalise our results beyond these limits.
- Some probabilities of progression were extrapolated beyond the follow-up periods cited in the literature and for advanced COAG to severe visual impairment there was no RCT data available.
- The methodology adopted by the study¹¹⁹ used as the source of health utilities in the model has not been validated yet. Also, the original health utilities¹² were estimated for different ocular conditions causing a defect in visual acuity. These utilities might not be applicable to glaucoma patients since the pattern of visual loss differs from other conditions. Furthermore, generic instruments such as the EQ-5D might not completely capture the quality of life decrement caused by small changes in visual ability.

The results of our model are applicable to OHT or COAG patients who have not been treated before. Although we have included data on IOP reduction in NTG patients, we could not find any evidence on the relationship between IOP reduction and progression reduction in this population. The results of our model might not be directly applicable to these patients.

Another assumption in our model was that the severity of OHT or COAG is similar in both eyes. However, in clinical practice a patient could present with unilateral COAG or OHT. We believe that the treatment should be established according to the worse eye if treated with medical therapy. In fact, a single bottle of drops per

month is used for treating either both eyes or one eye only as the bottle should be discarded after 28 days from the opening. In addition, since it is the patient who is being treated and not the eye, the cost of follow up visits and adverse events would be the same. Conversely, a surgical approach should be adopted only for the eye that requires it.

If the results of our economic analysis were adopted in the NHS, there would be an increase in surgical treatments with more pressure on Hospital Eye Services. However, if this was accompanied by a change in the referral scheme and monitoring provision, the resources freed up by the implementation of these policies could be used for the care of those patients requiring immediate treatment to prevent further progression. In addition, OHT patients with a low risk of progression would not be treated according to our model, which saves resources in terms of drugs and visits as well as patients not receiving treatment who would be monitored less frequently. On the other hand, OHT patients at a high risk for progression would receive prostaglandin analogues which are the most effective medical treatment. As a consequence, fewer people would develop COAG with less pressure on the Hospital Eye Service and the provision of surgery.

Another consequence of our results is that more emphasis would be given to the assessment of clinical parameters such as IOP and CCT for OHT patients and visual field defect for COAG patients.

Our findings are similar to those of previous studies: Kymes et al (2006)⁸⁰ and Stewart et al (2008)¹⁴⁴ found that treating all OHT patients is not cost-effective, while according to Kymes et al (2006)⁸⁰ selecting those with an elevated risk of conversion to COAG is a more cost-effective strategy (see Evidence Table – Appendix D). Le Pen et al (2005)⁸² explored the cost-effectiveness of prostaglandin analogues compared to beta-blockers in COAG patients through a Markov model reaching conclusions similar to our model (see Evidence Table – Appendix D).

1.3.19 Conclusions

- Treating all patients with OHT is not cost-effective.
- It is cost-effective to treat only OHT patients with IOP > 25 – 32 mmHg and CCT 555 – 590 μm with a beta-blocker until the age of 60 and OHT patients with IOP >21 and CCT $\leq 555\mu\text{m}$ with a prostaglandin analogue until the age of 80.

It is always cost-effective to treat COAG patients. However, trabeculectomy is cost-effective only when progression of visual field defect for Early COAG patients is >0.18 dB/per year – which is to say in the presence of any detectable progression. Trabeculectomy becomes more and more cost-effective the more advanced the stage of COAG.

1.4 NCC-AC cost analysis: Cost-effectiveness of tests

There is a wide variety of techniques and tests that are currently available for the assessment of clinical characteristics in order to diagnose and monitor OHT and COAG patients. Table 185 shows the clinical features and the relative tests used for their measurement which were included in our analysis.

Some of the tests are used for both diagnosis of OHT or COAG and monitoring. However, the importance of the result accuracy could vary between the two phases in the provision of care. CCT measurement for example is particularly important when diagnosing OHT in order to identify the relevant treatment strategy (1.3.17.1).

In our analysis, each test was compared only with the reference standard (marked in Table 185) used for the same clinical measurement.

Table 18 - Tests included in the economic analysis

Clinical Feature	Tests
IOP	Goldmann Applanation Tonometry*
	Non-contact tonometry (Pulse Air)
Optic Disc	Slit lamp biomicroscopy*
	Slit lamp biomicroscopy + stereoscopic disc photography

	Optical Coherence Tomography (OCT)

* Reference standard

1.4.1 General methodology

We found that the most practical approach for an economic evaluation was a cost analysis. In fact, estimating the consequences of false positives and false negatives

could be unattainable as there is uncertainty around the stage patients would be when undergoing the assessment and above all, around the time when they will be eventually correctly diagnosed. Another parameter that was not accounted for in our analysis is the time necessary to complete the tests. This exclusion is due to the following factors:

- the individual variability of the time to carry out the test,
- the consideration that while a test is being completed, the same healthcare professional could be involved in other activities,
- the variability of the opportunity cost depending on the type of healthcare professional who is performing the test,
- the GDG believed there are no substantial differences in times (with the exception of the 24-2 SITA standard Humphrey Visual Field test which we believe to be quicker than its comparators – see 1.4.5).

Consequently, we restricted our cost analysis to the calculation of capital costs, life span of the machines used, and the consumables.

We conducted a systematic search in order to identify published studies from the UK reporting cost data on the tests in Table 185 but we also relied on expert opinion and data provided by national suppliers (Haag-Streit). A study⁶⁶ was excluded because it was published in 1990 and so cost data were considered obsolete. Similarly, a decision model on screening¹⁵³ was excluded in which details of the tests which the costs refer to were not given. A HTA Kwartz et al (2005)⁷⁹ was selected as a possible source for the costs of HRT, Laser polarimetry, and Humphrey Visual Field Analyser.

Each clinical GDG member estimated the number of patients referred each year to a clinic for a confirmation of diagnosis and the number of follow-up visits. The mean of both the number of diagnostic visits and the number of follow-up visits were calculated.

Finally, we calculated the difference in cost per patient between tests measuring the same clinical feature.

Throughout the cost analysis, expert opinion was gathered from the GDG members.

1.4.2 Assumptions

The following assumptions were used in the cost analysis:

- The same test would be used for both diagnosis and monitoring
- Life span of machines is 5 years unless available data state differently
- Reference standard tests are the most accurate within the same group
- Interest rate for calculating the annual cost of machines is 3.5%
- Drugs used specifically for the test were the only consumables

1.4.3 Population

The number of patients referred every year to a clinic for confirmation/exclusion of COAG was estimated by averaging the estimates provided by the GDG (Table 186). The same method was applied to estimate the number of follow-up visits per year (Table 186). In other words, on average 3 patients per day undergo tests for the diagnosis of COAG and 33 patients per day are followed-up.

Table 19 - Population for tests

Diagnosis Population	Monitoring Population
1,000	12,000

In the cost analysis, the population for each test was the sum of diagnosis and monitoring population.

1.4.4 Resource use and costs

We could not find the capital cost of the machines used in all the tests compared. Those that were found were then used to calculate the annual cost based on the life span and the interest rate according to the formula:

$$\text{IX} \quad E = K / \{ [1 - (1+r)^{-n}] / r + 1 \}$$

where E = annual cost of the machine

K = capital outlay (cost of purchasing the machine)

r = interest rate 3.5%

n = life span

The capital cost of a Goldmann Tonometer is composed of the cost of the actual tonometer, the slit lamp on which it is mounted, and the lenses. Experts estimated the overall cost which was later confirmed by data provided by the UK supplier (personal communication). The latter also provided the average life span of the machine. The cost of a non-contact tonometer was obtained from the website of the UK distributor of Keeler Pulsair tonometer. The average life span was not available and therefore subject to assumption.

The same capital cost of the slit lamp as that which was estimated for the Goldmann Tonometer was used to calculate the cost of the slit lamp biomicroscopy test for the optic disc assessment. The cost of the HRT was found in the HTA⁷⁹ and confirmed by the UK supplier who gave us estimates of the life span as well. For the OCT we relied solely on supplier data while for the Laser Polarimetry the HTA⁷⁹ was the only available source and its life span was assumed to be 5 years. The cost of adding stereoscopic disc photography to the slit lamp examination was based on the cost of Monoscopic photography provided by the UK supplier (Haag-Streit).

No cost data were found on Visual Field tests with the exception of the Humphrey Visual Analyser. Therefore a cost analysis was not performed for this group of tests.

We obtained cost and life span data for Gonioscopy, A-scan, B-scan and OCT from the supplier. Van Herick's test is performed by means of a slit lamp, so only its cost was accounted for. Unfortunately, no cost data were obtained for the other tests.

Table 187 reports the parameters and the results of the calculation of annual costs of equipment according to the formula IX.

Table 20 - Annual cost of equipment

Machine/test	Capital outlay (K)	Life span (n)	interest rate (r)	ANNUAL COST (£)
IOP measurement				
Goldmann tonometry	10,000	15	3.5%	799
Non-contact tonometry	5,000	5	3.5%	907
Optic disc assessment				
Slit lamp biomicroscopy	10,000	30	3.5%	516
Slit lamp biomicroscopy + stereoscopic disc photography	10,000 (a)	7	3.5%	1,406
HRT	30,000	7	3.5%	4,271
OCT	45,000	7	3.5%	6,325
Laser polarimetry	30,000	5	3.5%	5,325
Anterior chamber angle assessment				
Gonioscopy	200 (b) + 10,000 (c)	3 (b) / 30 (c)	3.5%	569 (d)
A-scan	15,000	7	3.5%	2,108
B-scan	20,000	7	3.5%	2,811
OCT	28,000	7	3.5%	3,936
Van Herick	10,000 (c)	30	3.5%	516

(a) Only cost of monoscopic photography without slit lamp

(b) Gonioscope

(c) Slit lamp

(d) Total of gonioscope (£53) + slit lamp (£516)

Other resources considered in the cost analysis were drugs used in order to perform the test. One unit of Proxymetacaine and Fluorescein was used before Goldmann tonometry and Gonioscopy; whereas one unit of Tropicamide was used before Slit lamp biomicroscopy, HRT and OCT. The cost of a unit is calculated by dividing the cost of the pack by the number of units contained, as illustrated in Table 188 - Cost of drugs for tests

Table 21 - Cost of drugs for tests

Drugs	Cost Per Packa	Units	Cost Per Unit (£)
Proxymetacaine and Fluorescein	£7.95	20	0.4
Tropicamide	£5.75	20	0.3

(a) Source BNF 54

For each test, the total cost per patient was calculated as follows:

$$X \quad TC = ac/p + d$$

where

TC = total cost per patient

ac = annual cost of equipment

p = diagnosis and monitoring population

d = cost of drug unit (if applicable)

The incremental cost per patient of a test compared to the reference standard was calculated as follows:

$$IC = TC_c - TC_{rs}$$

where

IC = incremental cost

TC_c = total cost of the comparator

TC_{rs} = total cost of the reference standard

An exception was the estimation of the incremental cost of adding stereoscopic disc photography to sit-lamp biomicroscopy which is equivalent to the cost of the photography only as the slit lamp is present in both strategies.

1.4.5 Results of the cost analysis

The incremental cost of the reference standard compared to other tests was given by the difference in the total cost per patient, as reported in Table 189.

Results for the comparison between visual field tests could not be reported since we found cost data on tests other than Humphrey.

Non-contact tonometry is cost saving compared to the more accurate Goldmann tonometry, and similarly non-gonioscopic methods are less costly than Gonioscopy (Table 189). In contrast, tests for assessing optic disc are associated with increased costs (Table 189) without adding valuable or more accurate information on the clinical picture of the patient (expert opinion) when compared to the Slit lamp

biomicroscopic examination. On the other hand, adding stereoscopic disc photography to the slit lamp examination generates an additional cost per patient of 0.11 but could also provide useful information.

Table 22 - Results of cost analysis of tests

Test	Cost per patient (£)	Cost of test – cost reference standard (£)
IOP measurement		
Goldmann tonometry*	0.46	-
Non-contact tonometry	0.07	- 0.39 (cost saving)
Optic disc assessment		
Slit lamp biomicroscopy*	0.33	
Slit lamp biomicroscopy + stereoscopic disc photography	0.44	0.11
HRT	0.62	0.29
OCT	0.77	0.44
Laser polarimetry	0.41	0.08
Anterior chamber angle assessment		
Gonioscopy*	0.44	-
A-scan	0.16	-0.28 (cost saving)
B-scan	0.22	-0.22 (cost saving)
OCT	0.30	-0.14 (cost saving)
Van Herick	0.04	-0.40 (cost saving)

* Reference standard

1.4.6 Discussion

The first test that a patient receives at a diagnosis or monitoring visit is tonometry, which is a measurement of IOP. The Goldmann contact-tonometer is considered the reference standard. Whereas other non-contact tonometers are less costly (1.4.5) they are also less accurate. The consequences of obtaining a correct IOP measurement are closely connected to the identification of the most cost-effective treatment strategy (see 1.3). Therefore, despite its higher direct costs, Goldmann tonometry could be cost-effective compared to non-contact tonometry.

Anterior chamber angle assessment is fundamental at diagnosis in order to differentiate between open angle and angle closure glaucoma. It becomes less important at follow-up visits. Our analysis shows that gonioscopy is more costly than non-gonioscopic methods including Van Herick's test when omitting the cost of false referral and incorrect therapy initiation. Because of its elevated accuracy, it was the GDG's opinion that the reference standard cannot be substituted at diagnosis. However, for monitoring purposes van Herick's test could be sufficient. Gonioscopy is not extensively used in current practice and many optometrist practices in the community are not equipped to perform this test. Community Optometrists could

choose between purchasing a gonioscopy contact lens themselves and participating in a Hospital Eye Service (HES) scheme where this equipment would be provided.

Among the methods which are practical for routine use in the NHS, stereoscopic slit lamp biomicroscopy is considered the most reliable investigation to identify optic nerve damage from its appearance. In our cost analysis stereoscopic slit lamp examination turned out to be less costly than HRT, OCT and Laser Polarimetry. When this result is combined with its reputed greater accuracy, stereoscopic slit lamp biomicroscopy dominates the other tests. A further comparison in the analysis was made between the reference standard alone and the reference standard plus stereoscopic disc photography. This technology is not available in the current practice and to date it is only used in clinical trial settings. The additional costs that were found in the cost analysis (1.4.5) could be even higher since they correspond to the costs of monoscopic photography. Identifying optic disc damage is important for the correct diagnosis of COAG; if the damage is not identified the patient risks being discharged at serious risk of delayed diagnosis and treatment.

Our cost analysis has several limitations:

- We were not able to evaluate any estimate of effectiveness associated with each strategy; therefore a cost-effectiveness analysis could not be conducted.
- The cost of misdiagnosing OHT or COAG could be significant but was omitted because it would be very hard to estimate with reasonable precision. (The costs associated with correct diagnoses were also omitted).
- The harms caused by some tests (e.g. infections from Goldmann tonometer) and their costs were not included in the analysis.
- The final consideration on the accuracy of the tests (i.e. the reference standards are the most accurate) was largely based on expert opinion rather than on solid clinical evidence.

Unfortunately we did not find any study that carried out a similar economic analysis, thus we could not compare our findings with previous data.

1.4.7 Conclusions

- Goldmann tonometry and gonioscopy are considered the most accurate for the assessment of IOP and anterior chamber angle respectively. However they also generate more costs compared to non-contact tonometry and to non-gonioscopic methods.
- Stereoscopic slit lamp biomicroscopic assessment is considered the most accurate test for identifying optic nerve damage and it is also associated with less costs compared to HRT, OCT and Laser Polarimetry.
- These results should be treated with caution since the analysis has several limitations.

Appendix G

Recommendations for research

1.1 Recommendations for research on monitoring patients with OHT, COAG and suspected COAG

PICO question	Question: What is the clinical and cost effectiveness of different monitoring intervals for detection of disease progression in COAG patients at risk of progression?
Importance to patients or the population	Detection of progression of visual field damage in COAG is essential if treatments to prevent progression are to be instituted in time to avoid eventual deterioration to permanent severe visual impairment.
Relevance to NICE	<p>The answer to this question is key to guidance on chronic disease monitoring intervals in this guideline. Once diagnosed COAG patients face lifelong monitoring and treatment. Monitoring intervals tailored to the risk of progression for varying risk strata would allow more efficient use of available resources. Risk guided intervals would allow those at high risk of progression to receive more intensive monitoring and relieve the burden of unnecessary monitoring visits on those with slowly progressive disease. Resources would be more appropriately focused on those at greatest risk and with more effective early detection of progression, damage to vision over time may be minimised.</p> <p>With this information available NICE would be in a position to recommend risk guided monitoring intervals resulting in both better use of resources and better outcomes.</p>
Relevance to the NHS	The NHS would be in a better position to focus resources on those in most need. Early detection of progression followed by effective intervention would ultimately result in better visual outcomes and less costs associated with supporting visually impaired people (glaucoma currently accounts for ~10% of blind / partial sight registrations in England).
National priorities	Improving chronic disease management is currently an NHS priority ³³ . This DH policy document specifically identifies “Stratifying patients by risk” and “Aiming to minimise unnecessary visits” as 2 of its key priorities, each of which is relevant to this research question.

Current evidence base	No trial evidence was identified
Study design	<i>Design:</i> A randomised comparative trial of 3 perceived risk strata (rapid, medium, slow) for progression to be randomised to 2, 3 and 2 alternative monitoring intervals respectively. <i>Outcome:</i> Progression events detected.
Feasibility	The research would be ethically and technically feasible. The research costs would need to be considered in the context that participants would still need monitoring if outside a trial.
Other comments	The National Institute for Health Research (NIHR) might be a suitable funding source.
Importance	High. The research is essential to inform future updates of key recommendations in the guideline.

1.2 Recommendations for research on treatment for patients with COAG

1.2.1 Update of National survey of trabeculectomy

PICO question	What are the current NHS national benchmarks for surgical success and complications in patients with COAG undergoing trabeculectomy drainage surgery with and without pharmacological augmentation?
Importance to patients or the population	This would inform patients of what to expect from their surgery in terms of the chances of success and complications. It would provide more accurate and up to date evidence for surgical treatment in glaucoma.
Relevance to NICE	Changes in surgical technique, and therefore success and complication rates, could alter the economic model for glaucoma treatment resulting in potential changes in the NICE recommendations
Relevance to the NHS	Up to date information on surgical success and complication rates will provide benchmarks for clinical audit and assist in planning service provision.
National priorities	Not a national priority in term of NSF or white paper
Current evidence base	Current evidence base is the National Audit of Trabeculectomy. This is now 10 years old and techniques have changed. Some surgeons are advocating the use of other surgical techniques such as deep sclerectomy and drainage tube implants. The audit would set a standard against which newer techniques could be evaluated.
Study design	The study design should be the same as the Audit of 10 years ago so we can compare the outcomes now in the light of changes in technique and the recommendations made by that audit.
Feasibility	Technically, ethically and financially feasible
Other comments	<p>The research could be facilitated by the Royal College of Ophthalmologists.</p> <p>The National Institute for Health Research (NIHR) might be a suitable funding source.</p> <p>The Connecting for Health Information Centre may be a further source of support.</p>
Importance	High. The research is essential to inform future updates of key recommendations in the guideline.

1.2.2 Laser treatment

PICO question	What is the effectiveness and cost-effectiveness of initial argon, diode or selective laser trabeculoplasty treatment compared to PGA alone or laser + PGA in combination in COAG patients?
Importance to patients or the population	The comparative effectiveness and cost effectiveness of laser treatment compared to modern ocular hypotensive agents particularly PGAs are unknown but may offer a period of pressure control without the need for topical medications in some patients. In others, it may offer additional benefit to topical medications and in both cases there may be cost efficiencies and improved prevention of progression of the disease
Relevance to NICE	Because of the lack of evidence, the role of laser trabeculoplasty in COAG management cannot be clearly defined.
Relevance to the NHS	Knowledge of comparative effectiveness to modern medications may offer a significant gain in cost benefit and might lead to a major change in guidance for a significant proportion of newly diagnosed COAG patients
National priorities	Treatment of long term conditions
Current evidence base	A completed Cochrane systematic review clearly points to the need for up to date evidence as indicated above. Existing trials of laser trabeculoplasty compared to medical treatment refer to outdated pharmacological agents.
Study design	RCTs in primary research
Feasibility	The research would be ethically and technically feasible.
Other comments	MRC or NIHR would be suitable sources of funding as opposed to manufacturers of medicines or lasers. To enable double masking or at least single masking, some form of sham laser treatment will be needed.
Importance	High. The research is essential to inform future updates of key recommendations in the guideline.

1.3 Recommendations for research on service provision

PICO question	In patients identified on primary examination as exhibiting possible COAG, OHT or glaucoma suspect status, what is the comparative effectiveness of diagnosis by different healthcare professions?
Importance to patients or the population	High. Further involvement of non-medical healthcare professions in care of patients within the scope of this guideline has potential to increase available staff resource with the potential to improve access to care, both in terms of number of available clinicians and locations.
Relevance to NICE	An answer to this question might potentially alter the service deliver recommendations of the current guideline. This is important in the context of access to care.
Relevance to the NHS	High. The initial guideline recommends that patients within its scope receive care following diagnosis as well as the setting of a management plan, supervised by an NHS consultant ophthalmologist. This research recommendation aims to determine whether alternative options exist. Dependent on findings, it is possible that provision of care by non-medical professionals may impact the NHS in terms of cost and quantity of care available, and may require strategic service planning to determine future staffing requirements.
National priorities	Improving chronic disease management is currently an NHS priority ³³ . This DH policy document specifically identifies “Stratifying patients by risk” and “Aiming to minimise unnecessary visits” as 2 of its key priorities, each of which is relevant to this research question.
Current evidence base	The current available evidence base in the area is weak. One RCT exists, but is of limited generalisability due to its design.
Study design	A number of randomized controlled trials will be required.
Feasibility	The research would be ethically and technically feasible. However, due to the nature of the question, it is likely that projects in question will be large scale, require large sample sizes over extended time periods (years) and as such the research will be costly.
Other comments	No large scale service provision primary research on this subject area has been executed in over 10 years although the DH did pilot alternative glaucoma care pathways, demonstrating central government interest in this subject area.
importance	High: the research is essential to inform future updates of key recommendations in the guideline.

1.4 Recommendations for research on information for patients

PICO question	What is the clinical and cost effectiveness of providing glaucoma patients with a 'glaucoma card' or individual record of care compared to standard treatment?
Importance to patients or the population	Patient involvement in and understanding of management of glaucoma could reduce stress and uncertainty for patients and potentially improve compliance with medical treatment requirements, with resultant improved outcome i.e. prolonged sighted lifetime.
Relevance to NICE	This could provide evidence of better care in terms of outcome and patient experience. As such future NICE guidance would be in a position to recommend this more patient focused approach to care.
Relevance to the NHS	This could enable a significant increase in cost effectiveness by improving glaucoma management e.g. maximising the effectiveness of topical medical treatment across more patients.
National priorities	Improving chronic disease management is currently an NHS priority ³³ . This DH policy document specifically identifies "Stratifying patients by risk" and "Aiming to minimise unnecessary visits" as 2 of its key priorities, each of which is relevant to this research question.
Current evidence base	No RCTs or systematic reviews were identified in our literature review addressing this question.
Study design	Randomised controlled trial design with a qualitative component. The latter would be needed to develop both an appropriate intervention and patient focused outcome measure to assess patient experience. A standard visual function (field of vision) test would be appropriate for evaluation of visual outcome.
Feasibility	Ethically and technically feasible. The proposed studies would require significant sample size and duration to determine visual outcome with associated cost implications.
Other comments	Time scale to assess useful outcomes would be long, probably 5 years or more.
Importance	Medium. The research is relevant to the recommendations in the guideline but the research recommendations are not key to future updates. Anything that improves concordance with medications could help prolong a person's sight.
